

One Trusted Set of Numbers From Every System the Bank Runs.

A platform that collects the bank's data from every country and every source system, cleans and verifies it, reconciles it, turns it into the ratios the board and regulators care about, and makes sure every problem it finds is reviewed, approved and recorded.

Collect

every source, every country

Verify

cleaned, checked, reconciled

Measure

KPIs and regulatory views

Act

tasks, approvals, audit trail

Prepared for the Bank's CFO, COO, finance, risk and compliance teams.

From Many Systems to One Verified Truth.

A bank operating across several countries runs many systems, often a different mix in each country. Each holds part of the picture, in its own format. The platform brings them together into **one clean, checked and reconciled dataset**, with the numbers, the problems and the decisions in one place.

01 COLLECT AND CLEAN

It builds one dataset.

Every source is brought into Databricks, put into one standard format and checked record by record.

- Every record tagged with its source, country and run
- More than 25 quality checks
- Nothing lost without a trace

02 VERIFY AND MEASURE

It proves the numbers are right.

What each source sent is reconciled against what was kept, and the KPIs are calculated from verified data only.

- Reconciled per source, per country
- 9 fraud and business rules
- 8 headline KPIs, every night

03 ACT AND APPROVE

Every problem gets an owner.

Each issue becomes a task for the right team. Approved corrections flow back into the numbers on the next run.

- Tasks routed to the right team
- Second approval for large decisions
- Permanent audit trail

WHAT THE PLATFORM ADDS

Capabilities that today sit across people, files and inboxes.

One standard format

The same definitions for every country and every source system.

Proof, not trust

Every figure can be traced back to the source, file and run it came from.

Problems found automatically

Checks run on every record, every run, not on a sample.

Decisions on record

Who decided what, when and why, kept permanently.

ANY SOURCE, ANY COUNTRY

The source system is an input, never a constraint.

Files

CSV and spreadsheet exports dropped into a folder

Databases

Core banking and other systems read directly

Applications

ERPs and CRMs through their APIs

New countries

Added as a new source, not a new system

The demo runs on file drops today; connectors follow once the Bank confirms each country's systems (page 11).

Ten Countries. Ten Systems. No Single Version of the Truth.

Each country's systems record their own transactions correctly. But the questions the CFO and the regulator ask, **are the group's numbers complete, do they agree, and who fixed what**, can't be answered from any single one of them.

The systems of record

Core banking, ERPs, CRMs and spreadsheets in every country. Different formats, different codes, different cut-off times. Accurate on their own, but never checked against each other.

The decision

Capital, liquidity, credit risk and regulatory returns. Built from exports stitched together by hand, with no proof that nothing was lost, duplicated or changed on the way.

The platform closes the gap: one pipeline that collects every source, proves nothing was lost, and puts every exception in front of the right person.

Less time assembling, more time deciding. Collection, cleaning and calculation run automatically overnight, so finance starts the day with the numbers ready.

Built for a bank. Capital adequacy, liquidity, bad loans, IFRS 9 staging and regulatory returns are built into the platform, not bolted on.

Works with the systems the Bank has. The platform reads from existing systems. Nothing in them has to change or be replaced.

Eight Steps From Raw Data to an Approved Number.

Every run follows the same path. The first six steps run automatically in Databricks, in about ten minutes for the current data. **The last two involve people:** reviewing what the checks found, and approving the fixes.

Every Source In. Every Record Checked.

Each source delivers its data in its own shape. The platform reads it, converts it to one standard format, and then **checks every single record** before it is allowed anywhere near a KPI or a regulatory return.

WHAT IT REPLACES TODAY

Each country sends its figures in a different format. Someone copies them into a master spreadsheet, fixes dates and codes by hand, and removes rows that "look wrong". **Nobody can later prove which rows were removed, or why**, and one wrong currency code quietly changes a group total.

EVERY RECORD CARRIES ITS ORIGIN

TAG	EXAMPLE	USED FOR
Source system	Lebanon core banking	Reconciliation per source
Country	Lebanon	Country view, routing
Run and file	24 Sep run, accounts file	Tracing any number back

EXAMPLES OF THE CHECKS

CHECK	WHAT IT CATCHES
Missing values	A transaction with no amount, a customer with no risk rating
Invalid codes	Currency "XYZ", an unknown channel or customer segment
Impossible numbers	Negative balance, loan outstanding above its principal
Broken links	An account whose customer doesn't exist
Banking rules	A loan 90+ days overdue that isn't in IFRS 9 stage 3

A REAL EXAMPLE FROM THE DEMO DATA

Lebanon sent 755 transactions. 753 passed.

One had no amount, one used a channel the Bank doesn't have. Both were held back with their reason, the 4,000 USD difference was recorded, and a task was created for the CFO.

One format for every source

Dates, numbers and currency codes are standardised once, so every country is measured the same way.

Checked, not sampled

Every record in every run goes through every check. No record reaches a KPI without passing.

Rejected, never lost

A failing record is kept in a rejection log with the exact reason, so it can be fixed and brought back.

Traceable to the file

Any record can be traced to the source system, file and run it came from.

Unusual Activity Flagged. The Bank's KPIs Calculated.

Once the data is clean, two things happen in parallel: every transaction is screened for unusual patterns, and the figures the board and regulators watch are calculated. **Every number is computed from the verified data, never typed in.**

TRANSACTION SCREENING: THREE KINDS OF FLAG

Suspicious
Patterns that may point to fraud or money laundering: structuring just under a limit, money in and out the same day, a dormant account suddenly active.
Goes to: investigations

Threshold
A reporting event, not fraud: for example a single transaction above 50,000 USD.
Goes to: compliance

Operational
A processing fault, such as the same transaction posted twice.
Goes to: operations

Grouped into cases, not a flood of alerts. Related flags on the same account and day become one case with a severity. High and medium cases become tasks with a deadline; low ones go into a daily digest.

THE EIGHT HEADLINE KPIS, EVERY RUN

Capital adequacy CAR	Liquidity coverage LCR	Bad loans NPL ratio	Total assets in USD
Dollarization share in USD	Net interest margin NIM *	Cost-to-income efficiency *	Return on equity ROE *

Also calculated: loan book by product, segment, branch and currency · IFRS 9 staging · top 20 exposures · ageing · loan-to-value bands · branch, segment and country performance · the snapshot behind stress testing.

Limits and breaches. Each KPI is compared with its limit at three levels: early warning, internal appetite and regulatory minimum. A breach becomes a compliance task with a deadline.

* Uses a documented assumption until the Bank supplies the missing inputs (deposit rates, cost allocation, equity). Shown on screen with a footnote.

WHAT CHANGES FOR THE BANK

Fraud is not "a big number"
A large transaction is labelled a reporting event, not fraud. Each flag says why it was raised, so investigators start with a reason.

KPIs ready every morning
No one builds the ratios by hand. They are recalculated every run, on the same definitions, for every country.

Converted at a logged rate
Figures in LBP, SAR, QAR and EUR are converted to USD, and every exchange rate used is recorded with its time.

Hundreds of Differences. A Handful of Decisions.

Reconciliation answers two different questions, and the platform asks both on every run. Then, instead of sending people through differences one by one, it **clears the harmless ones, groups the rest by cause, and asks for one decision per group**.

CHECK A · RECEIVED VS KEPT, PER SOURCE

Did our own pipeline lose or change anything?

Rows received vs rows kept, and amounts per currency, for every source, country and table. Each gap is one CFO item, opening onto the rejected records.

SOURCE · DATA	RECEIVED	KEPT	RESULT
Lebanon · transactions	755	753	2 rows, 4,000 USD gap → CFO
Saudi Arabia · transactions	165	165	Matched

CHECK B · OUR DATA VS THE CORE BANKING SYSTEM

Does our copy agree with the Bank's system of record?

Every customer and account is compared field by field. A "break" is a value that disagrees, or a record on only one side.

BREAK	EXAMPLE
Value differs	Balance 294,618 in core banking vs 246,618 ours
Missing	A customer in core banking but not in our data

HOW DIFFERENCES BECOME DECISIONS

Every Exception Owned. Every Fix Approved.

A finding is only useful if someone acts on it. Every exception the platform finds becomes a **task with an owner, a priority and a deadline**, decided in one place, with a permanent record of who did what.

THE CFO APPROVAL LOOP FOR A RECONCILIATION GAP

WHO GETS WHAT

TASK	TEAM	DEADLINE
Reconciliation gap (received vs kept)	CFO	per item
Core-system difference (group)	Operations	1 day if important, else 3
Suspicious transaction case	Investigations	by severity
Threshold event, KPI breach	Compliance	by severity / limit
Data-quality problem, duplicate company	Operations	by severity

Teams, deadlines and limits are settings, not code. The values shown are placeholders until the Bank confirms them.

One queue for everyone
Every task type on one Tasks screen, with overdue items highlighted.

No one approves alone
Large decisions and the run sign-off need a second person.

Permanent audit trail
Every decision is logged, one entry per record, and can't be edited.

Source systems untouched
Corrections live in the platform's copy; the Bank's systems are only read.

WHAT CHANGES FOR THE BANK

No more email chains
The question, the evidence and the decision sit in the same task, instead of moving between people and files.

Fixes that stick
An approved correction is applied again on every run until the source itself is fixed, so it isn't overwritten overnight.

Audit-ready by design
For any number, the Bank can show where it came from, what was changed, and who approved it.

Not Just a Dashboard. One Place Where the Work Happens.

Eight screens, all reading the same verified numbers. Each role signs in and sees what it needs: **the board sees the ratios, finance sees the gaps, the reviewers see their tasks**, and nothing is re-keyed between them.

01 Executive summary The 8 KPI tiles coloured by limit, the trend, plain-language alerts, a country breakdown and Refresh Now. Click any tile to see what moved and why.	02 Portfolio and credit risk The loan book by product, segment, branch and currency, IFRS 9 staging, top 20 exposures, ageing and loan-to-value bands.	03 Branch and segment performance Branch league table, regional and segment results, and an efficiency chart showing which branches lead and which lag.	04 Scenario modelling Stress tests with four sliders (devaluation, rate change, bad-loan increase, deposit outflow) and base, adverse and severe presets.
05 Regulatory reporting Report calendar, reports in the regulator's layout, validation checks and PDF or Excel export. Every figure links back to its formula and source.	06 Reconciliation Received vs kept per source, and our data vs core banking: groups, every difference with filters, ageing, recurring items and the run sign-off.	07 Tasks The single to-do list: reconciliation groups, CFO items, suspicious cases, breaches and data problems, with deadlines and approvals.	08 Audit and oversight The permanent record of every decision, overdue work and who approved what, for internal audit and the regulator.

WHO SIGNS IN, AND WHAT THEY DO

Analyst Prepares the work and submits the day's reconciliation run for sign-off.	Reviewer Reviews and decides reconciliation groups, suspicious cases and alerts.	CFO (approver) Second approvals, run sign-off, reconciliation gaps and Refresh Now.	Administrator Limits, thresholds, teams and deadlines, all as settings.
--	--	---	---

A dashboard shows the number. A report describes what happened. **This platform is where the numbers are checked, explained and signed off.**

Ten Sources Today. A Hundred Tomorrow.

The processing runs on Databricks, which spreads work across as many machines as the data needs. Adding sources, countries or years of history **does not require a new platform, only more computing power**, which can be increased at any time and scaled back when the run is done.

01 MORE SOURCES

Each source is a configuration, not a rebuild.

A new country or system is one more source: a connection plus a mapping to the standard format. Checks, reconciliation, tasks and screens then apply automatically.

02 MORE DATA

More volume, more compute. Not more people.

Millions of transactions are handled by adding workers to the run. Heavier runs cost more compute; the steps and the results stay the same.

03 SAME SPEED ON SCREEN

The screens never touch the raw data.

Each run pre-calculates small summary tables, and the screens read only those. The design target is under two seconds per screen, whatever the volume underneath.

WHAT GROWS EASILY

- **Number of sources and countries:** 10, 20, 50 or 100
- **Data volume:** from thousands to millions of rows a night, by adding compute
- **New checks and rules:** thresholds and limits are settings, changed without code
- **New reports and screens:** built on the same verified data

WHAT EACH NEW SOURCE STILL NEEDS

- **A connector:** file drop, database or API, depending on how the system can share data
- **A mapping** of its fields and transaction codes to the standard format, confirmed by the Bank
- **Agreed record keys**, so the same customer or account is recognised across systems
- **Compute budget:** larger runs cost more; the Bank chooses the speed/cost balance

HOW THE SAME DESIGN CARRIES 10 OR 100 SOURCES

More fuel, more capacity: the design is the same at 10 sources or 100. The effort per new source is the mapping, not the platform.

Working End to End on Demo Data. Ready for the Bank's Systems.

The full flow, from file to approved correction, runs today on demo data in the Bank's format. Moving to production means connecting the Bank's real systems and replacing a small number of placeholder settings with the Bank's own values.

WORKING IN THE DEMO

- File-drop ingestion, standardisation and 25+ checks
- Source and country tagging on every record
- Received-vs-kept reconciliation per source, with completeness check
- 9 fraud and business rules, grouped into cases
- 8 KPIs, portfolio, branch, country and scenario figures
- Core-banking comparison with grouping and safety rules
- Tasks, CFO approval loop, second approval, audit trail
- All 8 screens, PDF and Excel export

BUILT, NEEDS THE BANK'S VALUES

- Official limits for each KPI and breach level
- Reconciliation tolerances and approval amounts
- Fraud and anti-money-laundering thresholds
- Teams, deadlines and task policy sign-off
- Inputs for NIM, cost-to-income and ROE
- Reporting currency and official FX source
- Refresh Now connection and daily schedule

NEXT, WITH THE BANK'S INPUT

- Connectors for each country's own systems (ERP, CRM, core banking)
- Field and transaction-code mapping per system
- Transaction-level matching against core banking
- Reconciliation against the general ledger and nostro statements
- Testing at full production volume

WHAT WE NEED FROM THE BANK TO GO LIVE

Systems per country

Which systems each of the 10 countries uses, and how each can share data: file, database or API.

Mappings and code lists

Field definitions and transaction codes for each system, and a shared customer and account identifier.

Limits and policies

Official KPI limits, tolerances, approval amounts, teams and deadlines.

What to reconcile against

Which systems the Bank reconciles today, for example core banking vs the general ledger.

No big-bang go-live. Start with one country, prove the numbers against what finance already trusts, then add country by country.

Thank you.

We would welcome an hour on the live demo with whoever you would like in the room: finance, risk, compliance or IT. We are equally happy to go deeper on any part of this document, answer questions in writing, or review the architecture and data security with anyone you nominate.
